(54) Title: COATING COMPOSITION, AND METHOD FOR MANUFACTURING HIGH SILICON ELECTRICAL STEEL SHEET USING THEREOF

(57) Abstract: There are provided a coating composition for siliconizing, and a method for manufacturing a high silicon electrical steel sheet using the same. The coating composition includes: a Fe-Si-based composite compound sintered powder having a grain size of - 325 mesh and containing 20 - 70 % silicon by weight; and a colloidal silica solution containing 15 - 30 part by weight of silica solid matter with respect to 100 part by weight of the sintered powder.

**COATING COMPOSITION, AND METHOD FOR MANUFACTURING HIGH  
SILICON ELECTRICAL STEEL SHEET USING THEREOF**

**TECHNICAL FIELD**

5           The present invention relates to a coating composition  
for siliconizing treatment of electrical steel sheets, and  
a method for manufacturing an electrical steel sheet using  
the same, and more specifically, to a coating composition  
for effectively siliconizing electrical steel sheets  
10 through a diffusion annealing process, and a method for  
manufacturing a high silicon electrical steel sheet having  
outstanding high frequency magnetic properties as well as  
outstanding commercial frequency properties by using the  
coating composition.

15

**BACKGROUND ART**

Electrical steel sheets are generally classified into  
grain-oriented electrical steel sheet and non-oriented  
electrical steel sheet. Grain-oriented electrical steel  
20 sheet contains 3% silicon (Si) and has a texture in which  
grains are oriented in an orientation  $\{ (110) [001] \}$ .  
Superior magnetic properties in the rolling direction allow  
these grain-oriented electrical steel sheet products to be  
used as core material of transformers, motors, generators  
25 and other electronic devices. Non-oriented electrical steel

sheet is characterized by orientations of grains being irregularly arranged and magnetic deviation according to magnetization direction being small. Due to these characteristics, the non-oriented electrical steel sheet is  
5 mainly used in a core for rotating machine such as generators or motors, in which magnetic flux direction is varied.

Recently, as electrical devices are diversified, demands on devices operating in high frequency band  
10 increase and thus desires on core material with superior magnetic properties in high frequency also start to increase.

In the meanwhile, in alloys of Fe-Si, since higher silicon contents allow hysteresis loss, magnetostriction, coersive force, and magnetic anisotropy among core loss  
15 properties to decrease and maximum permeability to increase, it is said that high silicon steel products are superior soft magnetic material. Then, the decrease of magnetostriction and the increase of maximum permeability  
20 do not continue limitlessly according to increase of silicon content but show maximum values in 6.5% Si steel. Also, it is well known that magnetic properties of 6.5% Si steel reach the maximum state in high frequency band as well as commercial frequency band. Due to the superior  
25 magnetic properties in high frequency band, high silicon

steel is mainly applicable to high frequency reactor for gas turbine generator, tank power supply, induction heating device, uninterruptible power supply, or the like, and high frequency transformer for plating power supply, welding machine, X-ray power supply or the like, and is being used as substitution material. In addition, the high silicon steel is applicable for use to reduce power consumption of a motor and improve the efficiency of the motor.

Then, since elongation of the silicon steel sheet decreases abruptly as silicon content in Fe-Si steel increases, it is known that it is nearly impossible to manufacture the silicon steel sheet containing in excess of 3.5% Si by a cold rolling. In spite of such a fact that higher Si contents are effective in obtaining superior magnetic properties, the manufacture of such a high silicon steel sheet is recognized as a limitation of the cold rolling. Accordingly, researches on a new substitution technology that can overcome the limitation of the cold rolling are being tried from a long time ago.

As prior arts known as methods that can manufacture high silicon steel sheets, Japanese Patent Laid Open Publication No. 56-3625, etc., discloses a direct casting of a high silicon steel using a single roll or twin rolls, Japanese Patent Laid Open Publication No. 62-103321, etc., discloses a warm rolling in which rolling is performed in a

heating state of a proper temperature, and Japanese Patent Laid Open Publication No. 5-171281, etc., discloses a clad rolling in which rolling is performed in a state that high silicon steel is located at an inner portion and low silicon steel is located at an outer portion. However, the  
5      aforementioned prior arts have been not yet commercialized.

For mass production of high silicon steel products such as 3% Si non-oriented steel products, there is well known a process including steps of depositing silicon on a  
10     surface of a material by a chemical vapor deposition using  $\text{SiCl}_4$  and then homogenizing the silicon in prior arts of Japanese Patent Laid Open Publication No. 62-227078, US Patent No. 3,423,253 and the like. However, the above process causes the produced products to be sold inevitably  
15     at a price five times higher than the conventional 3% Si steel products due to the difficulty in the CVD process. In spite that the produced products have superior magnetic properties, it is difficult to popularize and commercialize such products.

20       Also, EP1052043A2, JP2000192204, JP2000144248, JP200045025, etc. disclose processes for manufacturing high silicon steel sheets using powder metallurgy. However, these prior arts have a limitation in that high silicon content fails to manufacture a steel sheet with a desired  
25     thickness.

Further, USP 3,634,148, USP 4,073,668 and the like proposes a long-term annealing process in which Fe-Si alloy powder only or mixture powder of Fe-Si powder and binder is prepared, the mixture powder is rolled at a reduction ratio less than 5% and then annealed for a long term. However, the process to coat powder on matrix material and then apply a rolling process makes it difficult to perform cold rolling and is also not desirable in mass production system. Also, a low temperature long term annealing is not proper in mass production upon considering the productivity.

Among the currently circulated electrical steel products, only non-oriented electrical steel sheets containing 6.5% Si are produced and sold as the high silicon steel product. Owing to an irregular arrangement of grain, the non-oriented electrical steel sheets containing 6.5% Si content is used in the rotator with a small magnetic deviation according to magnetizing directions orientations. However, high silicon grain-oriented electrical steel sheet products, which demonstrate excellent characteristics in use for the transformer mainly using only the magnetic property in the rolling direction, have been not yet commercialized. Accordingly, various tries for producing a grain-oriented electrical steel sheet with superior magnetic properties due to high silicon content have been performed, but it has not been informed

yet on the success to produce such products.

#### DISCLOSURE OF THE INVENTION

Accordingly, the present invention has been made in an  
5 effort to solve the above-described problems of the prior  
arts.

An object of the invention is to provide a coating  
composition for effectively siliconizing electrical steel  
sheets through a diffusion annealing process.

10 Another object of the invention is to provide a method  
for manufacturing a high silicon electrical steel sheet  
having outstanding high frequency magnetic properties by  
coating the coating composition on a surface of the  
electrical steel sheet and diffusion annealing the coated  
15 steel sheet to thereby siliconize the electrical steel  
sheet.

To achieve the above object and other advantages and  
in accordance with the purpose of the invention, as  
embodied and broadly described herein, there is provided a  
20 coating composition including: a Fe-Si-based composite  
compound sintered powder having a grain size of -325 mesh  
and containing 20 - 70 % silicon by weight; and a colloidal  
silica solution containing 15 - 30 part by weight of silica  
solid matter with respect to 100 part by weight of the  
25 sintered powder.

In an aspect of the present invention, there is provided a method for manufacturing a high silicon electrical steel sheet, comprising the steps of: coating and drying the coating composition prepared as above on a surface of a steel sheet containing 2.0 - 3.3 wt% Si; and  
5 diffusion-annealing the dried steel sheet in a nitrogen gas atmosphere containing 20% or more hydrogen at a temperature range of 1000 - 1200 °C.

In another aspect of the present invention, there is provided, in a method for manufacturing a high silicon grain-oriented electrical steel sheet, comprising the steps of: reheating and hot-rolling a steel slab to produce a hot rolled steel sheet ; annealing the hot rolled sheet and cold- rolling the annealed steel sheet to adjust a  
15 thickness of the steel sheet; decarburization annealing the steel sheet; and secondary recrystallization annealing the steel sheet, the improved method further comprising the step of: picking(pickling) the surface of the grain-oriented electrical steel sheet where the secondary  
20 recrystallization is completed to remove a surface oxide layer; coating and drying the coating composition as described above on the surface of the pickled electrical steel sheet; and diffusion-annealing the dried electrical steel sheet in a nitrogen gas atmosphere containing 20% or  
25 more hydrogen at a temperature range of 1000 - 1200 °C.

In another aspect of the present invention, there is provided, in a method for manufacturing a high silicon non-oriented electrical steel sheet, comprising the steps of: reheating and hot-rolling a steel slab to produce a hot rolled steel sheet; annealing the hot rolled sheet and cold-rolling the annealed steel sheet to adjust a thickness of the steel sheet; recrystallization annealing the cold-rolled steel sheet, the improved method further comprising the step of: coating and drying the coating composition as described above on the surface of the cold rolled steel sheet; and diffusion-annealing the dried electrical steel sheet in a nitrogen gas atmosphere containing 20% or more hydrogen at a temperature range of 1000 - 1200 °C.

#### 15 BEST MODE FOR CARRYING OUT THE INVENTION

Hereinafter, the present invention will be described.

When contacting silicon (Si) containing metal with Fe metal under high temperature hydrogen or nitrogen atmosphere more than 950 °C, there occurs an interdiffusion reaction where Si atoms diffuse into Fe metal and Fe atoms diffuse into Si containing metal to make the concentration of Fe and Si in both sides to be identical. Accordingly, when contacting Si metal powder on surfaces of the electrical steel sheet and then annealing the electrical steel sheet at a high temperature, a difference in silicon

concentration causes an interdiffusion reaction where Si atoms are moved inside the steel sheet and Fe atoms of the steel sheet are moved toward the powder to be progressed.

When comparing the interdiffusion reaction of Fe atoms and Si atoms, since the diffusion rate of Si is approximately faster two times than that of Fe atoms in a temperature range of 1000 - 1200 °C, there occurs a phenomenon called Kirkendall effect corresponding to a non-homogeneous diffusion state. This non-homogeneous diffusion state causes non-homogeneous state defects at a reaction interface or creates various compounds such as  $\text{FeSi}_2$ ,  $\text{FeSi}$ ,  $\text{Fe}_5\text{Si}_3$  or  $\text{Fe}_3\text{Si}$ , which act as a factor deteriorating magnetic properties. Accordingly, it is in fact impossible to produce high silicon grain-oriented electrical steel sheets having homogeneous composition without surface defects by coating the silicon containing powder on the electrical steel sheet and diffusing Si atoms at a high temperature.

To solve the above problem, the inventor repeated researches on diffusion principle and so forth using Si powder and Fe powder, and finally found that the defects in the diffusion reaction portion are effectively removed not by using a coating composition including Si powder only as siliconizing agent but by using a coating composition of Fe-Si-based composite compound. Accordingly, the inventor

suggests the present invention.

In other words, the present invention provides a coating composition for siliconizing, and a method for manufacturing an electrical steel sheet using the same. The  
5 coating composition is composed to enable a diffusion where Si atoms and Fe atoms are substituted with each other by an identical amount without nearly forming an Fe-Si-bonded composite compound causing a surface defect at a diffusion reaction portion of the steel surface when the coating  
10 composition is coated on the surfaces of the electrical steel sheet and then annealed.

Unit technologies employed in the present invention to control diffusion amount of Si atoms will be concretely described in the below.

15 First, to further slack the diffusion rate of Si component, powder containing only Si metal is not used but Fe-Si-based compound such as  $\text{FeSi}_2$ ,  $\text{FeSi}$ ,  $\text{Fe}_5\text{Si}_3$  or  $\text{Fe}_3\text{Si}$  that Si metal is bonded to Fe metal is used as the main composition of the siliconizing coating agent. For this  
20 purpose, i.e., in order for the Fe-Si-based sintered powder to exist in a compound, the invention limits the Si content of the powder to 70 wt% or less.

Second, to suppress the diffusion of Si atoms, the grain size of Fe-Si-based sintered powder is made fine, and  
25 the fine Fe-Si-based sintered powder is coated on the

surface of the steel sheet, thereby reducing a surface contact area between the matrix material and the metal powder, i.e., interreaction area to 30% or less compared with a plate contact. Specifically, the present invention  
5 limits the grain size of the Fe-Si-based sintered powder to -324 mesh.

Third, to secure adhesion of Fe-Si-based annealed powder prepared as above to the surface of the matrix material and to secure coatability of the annealed powder,  
10 micro fine silica particles having a size corresponding to colloidal particle and a very excellent dispersity in water are added as binder of the coating composition.

Lastly, when the Fe-Si-based sintered powder is coated in a slurry state on surfaces of steel sheet and then  
15 annealed at a high temperature, the present invention controls atmosphere gas such that thin oxide film is formed on the surfaces of the steel sheet. This surface oxide layer acts as a hindrance film of the interdiffusion reaction to suppress diffusion of Si atoms toward the  
20 matrix material.

First, the inventive coating composition for siliconizing will be concretely described.

Fe-Si-based powder that is main component of the coating composition for siliconizing of the present  
25 invention can be manufactured by mixing Fe powder and Si

powder with each other, and sintering the mixed powder at a temperature range of 1000 - 1200°C in mixture gas atmosphere of hydrogen and nitrogen for 3 - 5 hours, but is necessarily not restricted thereto and can be manufactured by various methods. At this time, the component ratio of the sintered powder compound is changed depending on the mixed amount of Fe powder and Si powder. Theoretically, when the mixed amount is 50%Si+50%Fe, compound of  $\text{FeSi}_2$  is created, when the mixed amount is 34%Si+66%Fe, compound of  $\text{FeSi}$  is created, when the mixed amount is 25%Si+75%Fe, compound of  $\text{Fe}_5\text{Si}_3$  is created, and when the mixed amount is 14%Si+86%Fe, compound of  $\text{Fe}_3\text{Si}$  is created. However, in actual sintering, small amounts of several compounds may exist according to an initial mixing state. In particular, when a sintering reaction is generated by a mixing of Fe powder and Si powder, reaction is progressed in such a manner that Si atoms and Fe atoms are interdiffused to invade. Hence, although the amount of Si is somewhat large, the sintered powder becomes a state in which most of  $\text{FeSi}_2$  compound or  $\text{FeSi}$  compound corresponding to a state that Fe atoms have been diffused exist at the surfaces of the sintered powder and pure Si atoms exist at inside of the sintered powder. Accordingly, at most of the surface of the sintered powder, Fe-Si-based compound exist.

In the present invention, Si content in the Fe-Si-

based sintered powder obtained as above is restricted to 20 - 70 wt%. If the Si content is less than 20wt%, it is so small and thus diffusion rate may be very slow. Also, the high density of the sintered powder may cause the drop of the dispersion while the coating process is performed on the scene of production. Since the content of Si exceeding 70wt% allows main component to exist as  $\text{FeSi}_2$  and a mixture of extra metal Si phase, metal Si component contacts with the surface of material to increase the creation possibility of defects on surface during the siliconizing process so that the control of the silicon content as siliconized may be difficult. In other words, by restricting the Si content contained in Fe-Si-based sintered powder to a range of 20 - 70 wt%, it is possible to manufacture Fe-Si-based composite compound sintered powder having  $\text{FeSi}_2$ ,  $\text{FeSi}$ ,  $\text{Fe}_5\text{Si}_3$  or  $\text{Fe}_3\text{Si}$  as a main component. It is more preferable that the content of  $\text{FeSi}_2 + \text{FeSi}$  among the Fe-Si-based composite compounds should be restricted to 90wt% or more with respect to the total weight of the annealed powder.

Also, when preparing the aforementioned Fe-Si-based sintered powder in the present invention, it is preferable to form a thin oxide film on surfaces of the sintered powder during the sintering and cooling processes. The thin oxide film controls the diffusion rate of silicon during a

subsequent diffusion-annealing reaction, thereby suppressing defect creation in the surface of the matrix material and allowing products having excellent magnetic properties to be obtained.

5 More preferably, the oxygen content in the formed surface oxide film is limited to 2.0% or less. This is because the oxygen content exceeding 2.0% causes the diffusion rate of Si to be too slow.

10 In the meanwhile, to improve coatability and surface shape of matrix material in the present invention, it is preferably to add ultra fine  $\text{SiO}_2$  powder, alumina powder and alumina sol to the coating composition prepared as above.

More preferably, at least one selected from the group consisting of fine  $\text{SiO}_2$  powder, alumina powder and alumina  
15 sol is added by 0.2 - 3.5 part by weight with respect to 100 part by weight of the Fe-Si-based sintered powder having the aforementioned grain size and composition. If the added amount is less than 0.2 part by weight, improvement effect followed by the addition is weak. If the  
20 added amount exceeds 3.5 part by weight, surface properties may be deteriorated due to excessive coating amount.

When Fe-Si-based sintered powder manufactured as above is used as coating agent of electrical steel sheets, this powder is made in a slurry state and then coated on a  
25 surface of the steel sheet by using a roll coater, which is

most economical in production stage. The Fe-Si-based sintered powder as siliconizing agent should be made as fine as possible, which enhances the coating workability in a production stage and is advantageous in terms of management of surface shape on diffusion reaction. However, since the Fe-Si-based sintered powder where sintering reaction is completed is in a state of fused lump by a high temperature and long term reaction, it is necessary to control the grain size of the powder as fine as possible.

Accordingly, the present invention makes the grain size of Fe-Si-based sintered powder finely considering such a circumstance. Finer grain is advantageous in the coatability. Preferably, it is noted that the grain size should be restricted to -325 mesh upon considering the productivity and costs for formation of fine powder.

In the meanwhile, considering the actual coatability of the Fe-Si-based sintered powder prepared as above and the control of diffusion amount of Si as coated, the powder is dissolved in solvent to make a slurry solution, and then the prepared slurry solution is used as coating composition.

As the solvent, colloidal silica solution is used. At this time, silicon component is ultra fine  $\text{SiO}_2$  particles having a colloidal size. Since these ultra fine  $\text{SiO}_2$  particles are dispersed in water, when they are used mixed with other solid particles, viscosity of the slurry

solution can be increased to secure the coating workability.

In the present invention, it is preferable to add silica solution composed having 15 - 30 part by weight of silica with respect to the solid matter, to 100 part by weight of the Fe-Si-based powder. If the added amount is less than 15 part by weight, the coating composition shows a severe surface splitting due to the tension difference between the coating composition and the surface of the matrix material crevice, so that adhesion to the surface of the matrix material may be poor. If the amount exceeds 30 part by weight, the coatability is poor and the diffusion rate of silicon is too late during a subsequent homogenizing process so that a long-term annealing is needed, which is undesirable.

Next, a manufacturing process of an electrical steel sheet using the coating composition will be described.

The present invention manufacture high silicon electrical steel sheets by coating the aforementioned coating composition on electrical steel sheets manufactured by a conventional process and containing a predetermined content of silicon (preferably, containing 2.0 - 3.3 wt% silicon). In other words, the aforementioned coating composition is coated on surfaces of non-oriented electrical steel sheets as well as surfaces of grain-oriented electrical steel sheet manufactured by a

conventional process, and then annealed at a high temperature to thereby manufacture high silicon electrical steel sheets.

5 [Grain-oriented electrical steel sheet]

The manufacturing processes of the grain-oriented electrical steel sheet may show somewhat differences according to the manufacturers. However, the process generally includes the steps of: adjusting components in  
10 steel making; producing a steel slab from molten steel; reheating the steel slab; hot rolling the reheated steel slab; annealing a hot rolled sheet and cold rolling an annealed steel sheet to adjust the thickness of the steel sheet; decarburization annealing the steel sheet;  
15 performing a high temperature annealing of the steel sheet for a secondary recrystallization; and finish coating an insulating film. However, the invention is not limited to the above concrete manufacturing process and procedure. For instance, the inventive process may omit the hot rolled  
20 annealing step, or can be applied to a manufacturing process of an electrical steel sheet including the nitrizing step together with the decarburization annealing.

The products manufactured by the above process have a dual film structure consisting of a glass film (scientific  
25 name, forsterite,  $2\text{MgO} \cdot \text{SiO}_2$ ) and an insulating film formed

during the high temperature annealing. Also, there are glassless products in which special additive is added during a high temperature annealing to form a matrix layer where the formation of the glass layer is suppressed, and  
5 form an insulating film on the matrix layer.

In the present invention, the coating composition having the aforementioned composition can be coated on surfaces of a conventional grain-oriented electrical steel sheet where the secondary recrystallization is completed  
10 and thus basic magnetic properties are obtained. In other words, the object of the present invention can include all the grain-oriented electrical steel sheet products where the secondary recrystallization is completed, such as high temperature annealing plate, glassless steel sheet products  
15 and steel sheet products on which dual films are formed.

While the grain-oriented electrical steel sheet as the starting material of the invention essentially contains Si component, and may further contain necessary metals or non-metal element, such as Mn, Al, S, N and the like as an  
20 auxiliary agent according to the manufacturing process, the additive is not limited only to the aforementioned concrete components. It is more preferably noted that the grain-oriented electrical steel sheet on which the coating composition is being coated contains 2.9 - 3.3% Si with  
25 respect to the weight % of the steel sheet itself.

In the present invention, the surface film formed on the steel sheet which is subject to the secondary recrystallization annealing is removed by a pickling treatment, and then the coating composition having the  
5   aforementioned composition is coated on the steel sheet by a roll coater. At this time, the coated amount of the coating composition coated on the steel sheet is preferably determined by the below formulas 1 and 2:

$$Y - 5 \leq \text{coated amount} \leq Y + 5 \text{ ----- formula 1}$$

10    $Y(\text{g/m}^2) = 7650t(x_1 - x_2)/(A - 14.4) \text{ --- formula 2}$

Where 't' is thickness of matrix material, A is Si content (%) in the Fe-Si-based annealed powder, x1 is a target Si content (%) of matrix material, and x2 is an initial Si content of matrix material.

15   Thus, the steel sheet coated with the coating composition is preferably dried at a temperature range of 200 - 700 °C. If the drying temperature is less than 200 °C, the drying time is too long so that productivity is lowered. If the drying temperature exceeds 700 °C, oxide may be  
20   created on a surface of the steel sheet.

After that, the dried steel sheet is loaded in an annealing furnace and diffusion-annealed. At this time, the annealing temperature is restricted to 1000 - 1200 °C. If the annealing temperature is less than 1000 °C, siliconizing  
25   rate is too late so that a long time is taken for the

diffusion and the surface shape at the boundary of the siliconizing reaction is coarse and thus magnetic properties may be deteriorated. If the annealing temperature exceeds 1200 °C, reaction rate is too fast, surfaces of rolled coil are adhered to deteriorate the separation workability.

Accordingly, the diffusion annealing temperature is preferably restricted to 1050 - 1200 °C considering the surface shape at the boundary, and the workability.

Also, in the present invention, it is necessary to control the atmosphere gas in a nitrogen gas atmosphere containing 20% or more hydrogen gas during the diffusion annealing step. This is because if the hydrogen content is less than 20%, thin and dense SiO<sub>2</sub>-based oxide is formed on the matrix material so that the siliconizing reaction is hindered, and if Al component exists partly, in cooling after annealing, AlN is precipitated and thereby core loss can be abruptly deteriorated.

The diffusion annealing time is preferably restricted to 1 - 10 hours. If the diffusion annealing time is less than 1 hour, the siliconizing amount is small, and if the diffusion annealing time exceeds 10 hours, the siliconizing amount is excessive to make difficult a proper control, and an excessive long-term reaction may deteriorate the surface shape of the matrix material.

In the meanwhile, an insulating coating layer can be again formed on the surfaces of the siliconized steel sheet.

This insulating coating layer is formed by a conventional method in which an insulating coating agent prepared by mixing a small amount of chromic acid to mixture phosphate of magnesium (Mg), aluminum (Al) and Calcium (Ca), and colloidal silica component, is coated, or, is formed by coating organic/inorganic composite coating agent having chromate and acryl-based resin as main components for drawability. However, the present invention is not restricted only to the aforementioned concrete composition of the insulating coating agent.

[Non-oriented electrical steel sheet]

The manufacturing processes of the non-oriented electrical steel sheet may show somewhat differences according to the manufacturers, basic manufacturing process, or use. However, the process generally includes the steps of: adjusting components in steel making; producing a steel slab from the molten steel; reheating the steel slab; hot rolling the reheated steel slab; annealing a hot rolled sheet and cold rolling an annealed steel sheet) to adjust the thickness of the steel sheet; recrystallization annealing the cold-rolled steel sheet; and finish coating an insulating film. Various products for non-oriented

electrical steel sheet are being produced and sold depending on the manufacturing process, Si content, or level of magnetic properties.

In the present invention, the matrix material on which the aforementioned coating composition is being coated is a cold rolled steel sheet obtained by a cold rolling among the manufacturing steps of non-oriented electrical steel sheet. The cold rolled steel sheet is coated with the coating composition and then annealed at a high temperature so as to have a high silicon content. At this time, the cold rolled steel sheet preferably contains 2.0 - 3.3% Si with respect to the weight % of the steel sheet itself. This is because if the Si content is less than 2.0%, it takes a long time for siliconizing reaction using Fe-Si-based powder, which is a siliconizing agent, and is disadvantageous in economical aspect, if the Si content exceeds 3.3%, the steel sheet is brittle so that cold rolled capability is very poor.

In the present invention, the coating composition with the aforementioned composition is coated on the surfaces of the prepared steel sheet by a roll coater.

Herein, prior to coating the coating composition, it is desirable to perform an intermediate annealing of the cold rolled sheet plate. By performing temperature elevation and uniform heat treatment of the cold rolled

steel sheet in an intermediate annealing furnace where successive works are possible, texture of the matrix material is improved to thereby induce the optimization of initial magnetic properties. Also, by properly controlling the annealing atmosphere condition in the intermediate annealing, a thin and dense oxide film having faylite ( $\text{Fe}_2\text{SiO}_4$ ) as a main component is formed during a subsequent siliconizing step, and acts as a stop layer for suppressing the formation of  $\text{Fe}_3\text{Si}$ -based intermediate phase compound while Si component of Fe-Si-based sintered powder is diffused into the matrix material, so that surface shape, i.e., surface roughness, is improved and thus magnetic properties are improved compared with those as siliconized with an identical Si component.

At this time, it is desirable to restrict the intermediate-annealing temperature to 950 - 1100 °C. If the intermediate-annealing temperature is less than 950 °C, the improvement effect in the texture is deficient, and if the temperature exceeds 1100 °C, it is difficult to manage the facility.

Also, the intermediate annealing is preferably performed in a nitrogen atmosphere containing 50 % or more hydrogen and a moisture atmosphere where oxidization capability ( $\text{PH}_2\text{O}/\text{PH}_2$ ) referenced by dew point is adjusted in a range of 0.06 - 0.30. In a hydrogen atmosphere containing

less than 50%, it may be difficult to manage the oxidization capability and the control of the total oxygen content contained in the oxide. Also, if  $\text{PH}_2\text{O}/\text{PH}_2$  exceeds the range of 0.06 - 0.30, the hydrogen atmosphere fails to  
5 form faylite.

In the present invention, it is desirable to control the total oxygen content contained in the surface oxide layer of the intermediate-annealed steel sheet to 210 - 420 ppm. If the total oxygen content is less than 210 ppm, a  
10 capability for suppressing the creation of  $\text{Fe}_3\text{Si}$  that is an intermediate defect phase is deficient, and if the oxygen content exceeds 420 ppm, a large amount of  $\text{FeO}$  oxide film is formed on the faylite.

In the present invention, when the coating  
15 composition having the aforementioned composition is coated on surfaces of the cold rolled steel sheet or surfaces of the intermediated annealed steel sheet by a roll coater, the coated amount of the coating composition is preferably determined by the below formulas 1 and 2:

20 
$$Y - 5 \leq \text{coated amount} \leq Y + 5 \text{ ----- formula 1}$$

$$Y(\text{g/m}^2) = 7650t(x_1 - x_2)/(A - 14.4) \text{ --- formula 2}$$

Where 't' is thickness of matrix material, A is Si content (%) in the Fe-Si-based powder),  $x_1$  is a target Si content (%) of matrix material, and  $x_2$  is an initial Si  
25 content of matrix material.

Thus, the steel sheet coated with the coating composition is preferably dried at a temperature range of 200 - 700 °C. If the drying temperature is less than 200 °C, the drying time is too long so that productivity is lowered.

5 If the drying temperature exceeds 700 °C, oxide may be created on a surface of the steel sheet.

After that, the dried steel sheet is loaded in an annealing furnace and diffusion-annealed (homogenized). At this time, the annealing temperature is restricted to 1000

10 - 1200 °C. If the annealing temperature is less than 1000 °C, siliconizing rate is too late so that a long time is taken for the diffusion and the surface shape at the boundary of the siliconizing reaction is coarse and thus magnetic properties may be deteriorated. If the annealing

15 temperature exceeds 1200 °C, reaction rate is too fast, surfaces of rolled coil are adhered to deteriorate the separation workability.

Accordingly, the diffusion-annealing temperature is preferably restricted to 1050 - 1200 °C considering the

20 surface shape at the boundary, and the workability.

Also, in the present invention, it is necessary to control the atmosphere gas in a nitrogen gas atmosphere containing 20% or more hydrogen gas during the diffusion-annealing step. This is because if the hydrogen content is

25 less than 20%, thin and dense SiO<sub>2</sub>-based oxide is formed on

the matrix material so that the siliconizing reaction is hindered, and if Al component exists partly, in cooling after annealing, AlN is precipitated and thereby core loss can be abruptly deteriorated.

5       The diffusion-annealing time is preferably restricted to 1 - 10 hours. If the diffusion-annealing time is less than 1 hour, the siliconizing amount is small, and if the diffusion-annealing time exceeds 10 hours, the siliconizing amount is excessive to make difficult a proper control, and  
10 an excessive long-term reaction may deteriorate the surface shape of the matrix material.

After that, an insulating coating layer is formed on the surfaces of the siliconized steel sheet to thereby produce a final non-oriented electrical steel sheet product.  
15 In other words, non-reacted substances remaining on the surfaces of the siliconized steel sheet are removed and finally organic/inorganic composite coating agent having chromate and acryl-based resin as main components is coated, thereby producing a final high silicon non-oriented  
20 electrical steel sheet product. However, the present invention is not limited to the concrete composition of the insulating coating agent.

In the meanwhile, in the present invention, the coating composition composed as above can be naturally  
25 applied to the final non-oriented electrical steel sheet

product as well as the aforementioned cold rolled steel sheet under the aforementioned condition. However, if the coating composition is applied to the final products, a separate annealing process is required. Hence, in an aspect of omitting a manufacturing step, it is more preferable to use the cold rolled steel sheet as the matrix steel sheet on which the coating composition is being coated.

Hereinafter, the present invention will be described in more detail with embodiments. It is natural that the below embodiments should not be understood so as to restrict the technical scope of the invention.

#### Embodiment 1

Through a conventional manufacturing process of grain-oriented electrical steel sheet, there were prepared grain-oriented electrical steel sheet products each having a thickness of 0.23 mm and containing Si: 3.05% by weight, Mn: 0.12% by weight, Cu: 0.025% by weight, Cr: 0.13% by weight, P: 0.013% by weight, remnant Fe and inevitably contained impurity. After an insulating layer formed on the surfaces of the steel sheets prepared as above was removed, the steel sheets were coated with slurry solution formed by dispersing Fe-Si-based sintered powders having different grain sizes and compositions as shown in table 1 in

colloidal silica solution.

In the meanwhile, the used solvent colloidal silica solution is a 30% colloidal silica solution product sold in public. At this time, 20 part by weight of colloidal silica solution as referenced by the solid matter was mixed to 100 part by weight of Fe-Si-based powder.

The steel sheets coated with the Fe-Si-based powder were dried at a temperature of 400 °C, and after the coated state was visually observed, rolled in a large sized coil.

10 The rolled steel sheets were homogenized at 1125 °C in a nitrogen atmosphere containing 50% hydrogen for 4 hours. Afterwards, non-reacted substances remaining on the steel sheet where the siliconizing reaction was completed were removed and surface states were observed. Thereafter, an

15 insulation coating agent where a small amount of chromic acid was added to mixture phosphate of magnesium (Mg), aluminum (Al) and Calcium (Ca), and colloidal silica component, was coated on the steel sheets to form an insulation coating film, thereby manufacturing grain-

20 oriented electrical steel sheets on which the insulating coating layer is formed.

In the products manufactured as above, Si content and magnetic properties were examined. The magnetic properties, i.e., core loss and magnetic flux density (B<sub>8</sub>) were

25 examined by a single sheet measuring device, and are shown

in the below table 1. Herein,  $W_{10/50}$  represents the core loss at a frequency of 50 Hz and magnetic induction of 1.0 Tesla,  $W_{10/400}$  represents the core loss at a frequency of 400 Hz, 1.0 Tesla, and  $W_{5/1000}$  represents the core loss at a frequency of 1000 Hz, 0.5 Tesla, respectively. The magnetic flux density  $B_8$  represents magnetic flux per unit area, which is generated when being subject to a magnetizing force of 800A-turn/m, and matrix Si content is result values of wet analysis.

10

Table 1

No.	Fe-Si Powder		Coated state	Magnetic properties				Surface state	Matrix Si (%)
	Si (%)	Grain size (mesh)		$B_8$ (Tesla)	$W_{10/50}$ (W/Kg)	$W_{10/400}$ (W/Kg)	$W_{5/1000}$ (W/Kg)		
1	12	-325	Good	1.88	0.32	7.3	8.7	Good	3.7
2	25	-325	Good	1.79	0.30	6.7	7.4	Good	4.3
3	45	-325	Good	1.71	0.27	6.0	6.7	Good	5.8
4	62.5	-325	Good	1.69	0.26	5.8	6.4	Good	6.2
5	75	-325	Good	1.57	0.35	7.9	8.6	Small Hole	7.4
6	85	-325	Good	1.55	0.36	8.2	9.4	Hole	7.9
7	100	-325	Good	1.52	0.38	8.8	10.9	Hole	8.5
8	50	-150~+150	Thin	1.73	0.32	7.1	7.9	Defect	4.9
9	50	-250~+250	Non-uniform	1.71	0.32	6.9	7.5	Defect	5.2
10	50	-325	Good	1.70	0.27	6.1	6.4	Good	5.9
11	50	-450	Good	1.70	0.26	6.0	6.4	Good	6.0

As seen from table 1, the electrical steel sheets 2 to 4, 10 and 11 controlled to have a proper silicon content in the Fe-Si-based sintered powder were increased in silicon content and thus showed superior core loss

properties in high frequency band as well as in commercial frequency band. Also, they showed superior coating states.

On the contrary, the electrical steel sheet 1 having a small silicon content in the Fe-Si-based sintered powder was too small in silicon content as siliconized so that improvement effect in magnetic properties was poor. In case of the electrical steel sheets 5 to 7 containing 70% or more Si, silicon content was large but defect such as hole was generated so that magnetic properties of the steel sheet were weakened.

In case of the electrical steel sheets 8 and 9, which are outside the grain size range of the invention, as coated in slurry state, they were thin and non-uniform in thickness, so that silicon content in the steel sheets was small and many defects were observed on the surfaces of the steel sheets, which represents a relatively low quality that the improvement in the magnetic properties was very small and the magnetic properties were deteriorated.

## Embodiment 2

Steel slabs each containing Si: 2.9% by weight, Mn: 0.022% by weight, Al: 0.3% by weight, Sn: 0.025% by weight, P: 0.003% by weight, C: 0.0025% by weight, S: 0.0011% by weight, N: 0.0003% by weight, remnant Fe and inevitably contained impurity were reheated at a temperature of 1220 °C, and then hot-rolled to produce hot rolled steel sheets. The

hot rolled steel sheets were annealed for five minutes at 1000 °C and pickled. After the hot rolled steel sheets were cold rolled so as to have a final thickness of 0.20 mm, rolling oil coated on the surface thereof was removed.

5       The steel sheets were coated with slurry solution formed by dispersing Fe-Si-based sintered powders composed as shown in table 2 in colloidal silica solution. The used colloidal silica solution herein is a 30% colloidal silica solution product sold in public. At this time, 20 part by  
10 weight of colloidal silica solution as referenced by the solid matter was mixed to 100 part by weight of Fe-Si-based powder.

      The steel sheets coated with the Fe-Si-based powder were dried at a temperature of 400 °C, and the coated state  
15 was visually observed. After that, the dried steel sheets were rolled in a large sized coil. The rolled steel sheets were diffusion annealed at 1125 °C in a nitrogen atmosphere containing 50% hydrogen for 4 hours. Afterwards, non-  
reacted substances remaining on the steel sheet where the  
20 siliconizing reaction was completed were removed and surface states were observed. Thereafter, organic/inorganic composite coating agent having chromate and acryl-based resin as main components was coated to thereby manufacture non-oriented electrical steel sheets on which the  
25 insulating coating layer is formed.

In the products manufactured as above, Si content and magnetic properties were examined, and shown in the below table 2. The evaluation standards of the concrete properties are the same as those of embodiment 1.

5

Table 2

No.	Fe-Si powder		Coated state	Magnetic properties				Surface state	matrix Si (%)
	Si (%)	Grain size (mesh)		B <sub>8</sub> (Tesla)	W <sub>10/50</sub> (W/Kg)	W <sub>10/400</sub> (W/Kg)	W <sub>5/1000</sub> (W/Kg)		
1	12	-325	Good	1.46	0.80	11.45	11.06	Good	3.5
2	25	-325	Good	1.38	0.72	10.24	10.01	Good	4.2
3	50	-325	Good	1.32	0.64	9.14	8.98	Good	5.6
4	62.5	-325	Good	1.28	0.62	8.52	8.43	Good	6.0
5	75	-325	Good	1.23	0.71	11.02	11.23	작은 Hole	6.8
6	85	-325	Good	1.21	0.73	11.11	11.52	Hole	7.1
7	100	-325	Good	1.20	0.74	11.36	12.02	Hole	7.7
8	50	-150~+250	Thin	1.36	0.70	10.12	9.96	Defect	4.5
9	50	-250~+325	Non-uniform	1.35	0.68	9.88	9.75	Defect	4.8
10	50	-325	Good	1.31	0.64	9.03	8.82	Good	5.7
11	50	-450	Good	1.26	0.61	8.50	8.41	Good	6.1

As seen from table 2, the electrical steel sheets 2 to 10 4, 10 and 11 controlled to have an optimum grain size and composition in the Fe-Si-based sintered powder were increased in silicon content and thus showed superior core loss properties in high frequency band as well as in commercial frequency band. Also, they showed good coating

states.

On the contrary, the electrical steel sheet 1 having a very small silicon content was too small in silicon content as siliconized so that improvement effect in magnetic properties was poor. In case of the electrical steel sheets 5 to 7 containing 70% or more Si, silicon content was large but defect such as hole was generated so that magnetic properties of the steel sheet are weakened.

In the meanwhile, in case of the electrical steel sheets 8 and 9, which are outside the grain size range of the invention, they were thin and non-uniform in thickness, so that silicon content in the steel sheets was small and many defects were observed on the surfaces of the steel sheets, which represents a relatively low quality that the improvement in the magnetic properties was very small and the magnetic properties were deteriorated.

### **Embodiment 3**

From steel slabs each containing C: 0.0020% by weight, Si: 3.15% by weight, Mn: 0.014% by weight, P: 0.025% by weight, N: 0.0002% by weight, S: 0.0003% by weight, remnant Fe and inevitably contained impurity, grain-oriented electrical steel sheet products having a thickness of 0.23 mm were manufactured by using AlN component as main inhibitor. After that, the surfaces of the steel sheets were treated in acid solution to completely remove the

surface insulating layer.

After that, the steel sheets were coated with coating composition for siliconizing formed in a slurry state by dispersing Fe-Si-based sintered powders composed as shown  
5 in table 3 in colloidal silica solution.

In the meanwhile, the Fe-Si-based sintered powder used herein was manufactured by mixing Si powder and Fe powder with varying the mixing ratio in a range of 9 - 75% and sintering the mixture powder at a temperature of 1100 -  
10 1175 °C for five hours, and then being made in a grain size less than 325 mesh. Also, the colloidal silica solution used herein is a 30% colloidal silica solution product sold in public, and silica solid matter was controlled in a range shown in table 3 and then used.

15 The steel sheets coated with the coating composition were dried at a temperature of 400 °C, and the coated state was visually observed. After that, the dried steel sheets were coiled in a large sized coil. The coiled steel sheets were diffusion annealed at 1125 °C in a nitrogen atmosphere  
20 containing 50% hydrogen for 4 hours. Afterwards, non-reacted substances remaining on the steel sheet where the siliconizing reaction was completed were removed and then an insulation coating agent where a small amount of chromic acid was added to mixture phosphate of magnesium (Mg),  
25 aluminum (Al) and Calcium (Ca), and colloidal silica

component, was coated on the steel sheets to form an insulation coating film, thereby manufacturing final high silicon grain-oriented electrical steel sheets on which the insulating coating layer is formed.

5 In the products manufactured as above, Si content and magnetic properties were examined, and shown in the below table 3. The evaluation standards of the concrete properties are the same as those of embodiment 1.

10 Table 3

No.	Fe-Si powder		c.SiO <sub>2</sub> added amount (g)	Coated state	Magnetic properties				Matrix Si content (%)
	Si Conte nt (%)	Added Amount (g)			B <sub>8</sub> (Tesla)	W <sub>10/50</sub> (W/Kg)	W <sub>10/400</sub> (W/Kg)	W <sub>5/1000</sub> (W/Kg)	
1	-				1.92	0.31	7.6	9.2	3.1
2	9	100	25	Thin	1.90	0.31	7.4	9.1	3.4
3	20	100	25	Good	1.85	0.28	6.8	7.5	4.0
4	50	100	25	Good	1.69	0.25	5.6	6.2	6.3
5	75	100	25	Thick	1.54	0.36	8.4	10.7	7.5
6	40	100	10	Delami nation	1.48	0.33	7.9	9.9	6.9
7	40	100	25	Good	1.71	0.26	5.8	6.3	5.8
8	40	100	40	Thin	1.87	0.29	7.3	8.8	3.5

As seen from table 3, compared with the electrical steel sheet 1 corresponding to the conventional material, the electrical steel sheets 3, 4 and 7 controlled to have a proper composition in the Fe-Si-based powder were greatly

increased in silicon content and thus showed superior core loss properties in high frequency band of 400Hz and 1000Hz as well as in commercial frequency band.

On the contrary, the electrical steel sheet 2 having a very small silicon content was too small in coating amount and silicon content as siliconized so that improvement effect in magnetic properties was poor. In case of the electrical steel sheet 5 containing too much Si, silicon content was large but surface state is coarse so that core loss characteristics were rather deteriorated.

Also, in case of the electrical steel sheet 6 having a relatively small silica content, delamination of the coated film was severe and core loss characteristics were rather deteriorated. In case of the electrical steel sheet 8, the added amount of the colloidal silica was too much, the coated amount of the coating composition was small and silicon content as siliconized was small so that the improvement effect in the magnetic properties was small.

#### Embodiment 4

Steel slabs each containing C: 0.0015% by weight, Si: 2.95% by weight, Mn: 0.022% by weight, P: 0.003% by weight, Ni: 0.012% by weight, N: 0.0006% by weight, S: 0.0011% by weight, remnant Fe and inevitably contained impurity were reheated at a temperature of 1220 °C, and then hot-rolled annealed to produce hot rolled steel sheets having a

thickness of 2.5 mm. The hot rolled steel sheets were annealed for five minutes at 1000 °C and pickled. After the hot rolled steel sheets were cold rolled so as to have a final thickness of 0.20 mm, rolling oil coated on the surface thereof was removed.

First, one of the cold rolled steel sheets obtained as above was recrystallization-annealed at 1020 °C in a nitrogen atmosphere containing 25% hydrogen for 2 minutes like the conventional manufacturing process of non-oriented electrical steel sheet. For comparison with the conventional steel sheets, coating composition was coated as shown in table 4 on the surfaces of the plurality of cold rolled steel sheets obtained as above.

In the meanwhile, the Fe-Si-based powder used herein was manufactured by mixing Si powder and Fe powder with varying the mixing ratio in a range of 10 - 80% and sintering the mixture powder at a temperature of 1100 - 1175 °C for five hours, and then being made in a grain size less than 325 mesh. Also, the colloidal silica solution used herein is a 30% colloidal silica solution product sold in public, and silica solid matter was controlled in a range shown in table 4 and then used.

The steel sheets coated with the coating composition were dried at a temperature of 400 °C, and the coated state of the surfaces was visually observed. After that, the

dried steel sheets were coiled in a large sized coil. The coiled steel sheets were homogenized at 1150 °C in a nitrogen atmosphere containing 75% hydrogen for 5 hours. Afterwards, non-reacted substances remaining on the steel sheet where the siliconizing reaction was completed were removed and surface states were observed. Thereafter, organic/inorganic composite coating agent having chromate and acryl-based resin as main components was coated to thereby manufacture non-oriented electrical steel sheets on which the insulating coating layer is formed.

In the products manufactured as above, Si content and magnetic properties were examined, and shown in the below table 4. The evaluation standards of the concrete properties are the same as those of embodiment 1.

Table 4

No.	Fe-Si powder		c.SiO <sub>2</sub>	Coated state	Magnetic properties				matrix Si content (%)
	Si Content (%)	Added amount (g)	Added amount (g)		B <sub>8</sub> (Tesla)	W <sub>10/50</sub> (W/Kg)	W <sub>10/400</sub> (W/Kg)	W <sub>5/1000</sub> (W/Kg)	
1			-		1.46	0.85	11.95	11.61	2.9
2	10	100	20	Thin	1.49	0.85	11.72	11.53	3.0
3	25	100	20	Good	1.38	0.71	10.05	9.78	4.3
4	55	100	20	Good	1.27	0.59	8.47	8.26	6.4
5	80	100	20	Thick	1.23	0.73	12.03	12.35	7.1
6	40	100	10	Delamination	1.24	0.72	11.89	12.03	6.9
7	40	100	25	Good	1.33	0.64	9.24	8.96	5.5
8	40	100	40	Thin	1.45	0.82	11.35	11.22	3.4

As seen from table 4, compared with the electrical steel sheet 1 corresponding to the conventional material, the electrical steel sheets 3, 4 and 7 controlled to have a proper composition in the Fe-Si-based powder were greatly  
5 increased in silicon content and thus showed superior core loss properties in high frequency band of 400Hz and 1000Hz as well as in commercial frequency band.

On the contrary, the electrical steel sheet 2 having a very small silicon content was too small in coating amount  
10 and silicon content as siliconized so that improvement effect in magnetic properties was poor. In case of the electrical steel sheet 5 containing too much Si, silicon content was large but surface state is coarse so that core loss characteristics were rather deteriorated.

Also, in case of the electrical steel sheet 6 having a relatively small silica content, delamination of the coated film was severe and core loss characteristics were rather deteriorated. In case of the electrical steel sheet 8, the added amount of the colloidal silica was too much, the  
15 coated amount of the coating composition was small and  
20 silicon content as siliconized is small so that the improvement effect in the magnetic properties was small.

#### Embodiment 5

25 The grain-oriented electrical steel sheets described in the embodiment 3 were prepared as matrix material. Also,

coating composition for siliconizing was prepared by mixing colloidal silica solution to 100 part by weight of Fe-Si-based fine powder containing 50% Si, the colloidal silica solution being composed such that silica has 25 part by weight with respect to the weight of the solid matter. The prepared coating composition was coated on the surfaces of the matrix steel sheets by using a roll coater. The coated steel sheets were dried at a temperature of 400 °C, and were coiled in a large sized coil.

The coiled steel sheets were homogenized with varying the annealing condition as shown in table 5 to thereby remove non-reacted substances remaining on the surfaces of the steel sheets. Then, an insulation coating agent where a small amount of chromic acid was added to mixture phosphate of magnesium (Mg), aluminum (Al) and Calcium (Ca), and colloidal silica component, was coated on the steel sheets to form an insulation coating film, thereby manufacturing final high silicon grain-oriented electrical steel sheets on which the insulating coating layer is formed.

In the products manufactured as above, Si content and magnetic properties were examined. The evaluation standards of the concrete properties are the same as those of embodiment 1.

No.	Diffusion annealing conditions		Magnetic properties				Matrix Si content (%)
	Hydrogen ratio (%)	Temp. (°C)	B <sub>8</sub> (Tesla)	W <sub>10/50</sub> (W/Kg)	W <sub>10/400</sub> (W/Kg)	W <sub>5/1000</sub> (W/Kg)	
1	0	1125	1.89	0.30	7.5	9.3	3.3
2	10	1125	1.84	0.29	7.3	8.8	3.6
3	25	1125	1.73	0.26	6.0	6.3	5.4
4	90	1125	1.72	0.25	5.8	6.2	5.7
5	50	950	1.92	0.34	7.9	9.6	3.1
6	50	1100	1.74	0.27	5.9	6.2	5.4
7	50	1225	1.56	0.36	6.8	7.3	6.1
8	75	1125	1.70	0.24	5.7	6.3	5.9

As seen from table 5, the electrical steel sheets 3, 4, 6 and 8 controlled to have a proper homogenizing condition were increased in silicon content of matrix and thus showed superior core loss properties in high frequency band as well as in commercial frequency band.

On the contrary, the electrical steel sheets 1 and 2 which were homogenized in 100% nitrogen gas atmosphere and in a nitrogen gas atmosphere containing 10% hydrogen had a poor increase in Si content of matrix material so that improvement in core loss characteristics was deficient.

Also, in case of the electrical steel sheet 5 having a too low annealing temperature, there was nearly no variation in Si content in the matrix material so that high silicon electrical steel sheets were not obtained. In case of the electrical steel sheet 7 annealed at a high

temperature of 1225 °C, surface defect was generated so that core loss characteristics in commercial frequency were deteriorated.

5        **Embodiment 6**

The grain-oriented electrical steel sheets described in the embodiment 4 were prepared as matrix material. Also, coating composition for siliconizing was prepared by mixing colloidal silica solution to 100 part by weight of Fe-Si-  
10 based fine powder containing 50% Si, the colloidal silica solution being composed such that silica has 25 part by weight with respect to the weight of the solid matter. The prepared coating composition was coated on the surfaces of the matrix steel sheets by using a roll coater. The coated  
15 steel sheets were dried at a temperature of 400 °C, and were coiled in a large sized coil.

The coiled steel sheets were diffusion annealed with varying the annealing condition as shown in table 6 to thereby remove non-reacted substances remaining on the  
20 surfaces of the steel sheets. Then, organic/inorganic composite coating agent having chromate and acryl-based resin as main components was coated to thereby manufacture final non-oriented electrical steel sheets on which the insulating coating layer was formed.

25        In the products manufactured as above, Si content and magnetic properties were examined. The evaluation standards

of the concrete properties are the same as those of embodiment 1.

Table 6

5

No.	Diffusion annealing conditions		Magnetic properties				Matrix Si content (%)
	Hydrogen ratio (%)	Temp. (°C)	B <sub>8</sub> (Tesla)	W <sub>10/50</sub> (W/Kg)	W <sub>10/400</sub> (W/Kg)	W <sub>5/1000</sub> (W/Kg)	
1	0	1150	1.49	0.84	11.68	11.48	3.0
2	10	1150	1.46	0.81	10.98	10.88	3.4
3	25	1150	1.35	0.68	9.48	9.13	5.0
4	90	1150	1.34	0.67	9.41	9.07	5.3
5	50	950	1.48	0.85	11.70	11.34	3.0
6	50	1100	1.35	0.71	9.55	9.31	4.9
7	50	1225	1.23	0.86	11.34	11.01	5.8
8	75	1150	1.33	0.63	9.18	8.88	5.7

As seen from table 6, the electrical steel sheets 3, 4, 6 and 8 controlled to have a proper diffusion annealing condition were increased in silicon content of matrix and thus showed superior core loss properties in high frequency band as well as in commercial frequency band.

On the contrary, the electrical steel sheet 1 which was diffusion annealed in 100% nitrogen gas atmosphere and in a nitrogen gas atmosphere containing 10% hydrogen had a poor increase in Si content of matrix material so that improvement in core loss characteristics was deficient.

Also, in case of the electrical steel sheet 2 having a too low annealing temperature of 950 °C, there was nearly no variation in Si content in the matrix material so that high silicon electrical steel sheets were not obtained. In case of the electrical steel sheet 7 annealed at a high temperature of 1225 °C, surface defect was generated so that core loss characteristics in commercial frequency were deteriorated.

#### Embodiment 7

Steel slabs each containing C: 0.0018% by weight, Si: 3.02% by weight, Mn: 0.020% by weight, P: 0.003% by weight, Ni: 0.010% by weight, N: 0.0005% by weight, S: 0.0010% by weight, remnant Fe and inevitably contained impurity were reheated at a temperature of 1220 °C, and then hot-rolled to produce hot rolled steel sheets having a thickness of 2.5 mm. The hot rolled steel sheets were annealed for five minutes at 1000 °C and pickled. After the hot rolled steel sheets were cold rolled so as to have a final thickness of 0.20 mm, rolling oil coated on the surface thereof was removed.

The cold rolled steel sheets produced as above were intermediate-annealed under conditions shown in table 7. The intermediate-annealed steel sheets were coated with coating composition formed in a slurry state by mixing colloidal silica solution to 100 part by weight of Fe-Si-based sintered powder containing 45wt% Si, the colloidal

silica solution being composed such that the solid matter of silica has 25 part by weight with respect to 100 part by weight of Fe-Si-based sintered powder. The coated steel sheets were dried at a temperature of 400 °C, and were coiled in a large sized coil. After that, the dried steel sheets were homogenized at 1125 °C in a nitrogen atmosphere containing 50% hydrogen for 5 hours. Afterwards, non-reacted substances remaining on the steel sheet where the siliconizing reaction was completed were removed.

Thereafter, organic/inorganic composite coating agent having chromate and acryl-based resin as main components was coated to thereby manufacture final high silicon non-oriented electrical steel sheets on which the insulating coating layer was formed.

In the products manufactured as above, Si content and magnetic properties were examined. The evaluation standards of the concrete properties are the same as those of embodiment 1. Only, it is noted that matrix Si content is result values of wet analysis.

Table 7

No.	Intermediate annealing condition				Magnetic properties			Matrix Si content (%)
	Temp. (°C)	H <sub>2</sub> (%)	PH <sub>2</sub> O /PH <sub>2</sub>	Oxygen content (ppm)	B <sub>8</sub> (Tesla)	W <sub>10/50</sub> (W/Kg)	W <sub>5/1000</sub> (W/Kg)	
1	1050	75	0.09	240	1.27	0.57	8.22	6.3
2	1050	75	0.28	380	1.27	0.59	8.24	6.3

3	1075	75	0.25	350	1.27	0.58	8.22	6.2
4	1000	75	0.25	350	1.26	0.58	8.24	6.3
5	1050	50	0.25	380	1.27	0.58	8.21	6.3
6	1050	90	0.25	375	1.27	0.57	8.20	6.4

As seen from table 7, cold-rolled steel sheets were intermediate-annealed, coated with coating composition, and then annealed at a high temperature so that non-oriented  
5 electrical steel sheets were manufactured.

Although the present invention has been shown and described with reference to the above preferred embodiment, it is not to be understood that the invention is limited thereto. Rather, it will be apparent to those skilled in  
10 the art that various modifications and changes may be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

#### INDUSTRIAL APPLICABILITY

15 As described above, the present invention uses Fe-Si-based sintered powder with an optimally adjusted composition as well as grain size, as coating agent for siliconizing, so that final electrical steel sheets have a high silicon content and accordingly it is possible to  
20 effectively manufacture a high silicon electrical steel sheet having superior magnetic properties in commercial frequency and high frequency bands.

## CLAIMS

1. A coating composition for siliconizing, comprising:

5 a Fe-Si-based composite compound sintered powder having a grain size of -325 mesh and containing 20 - 70 % silicon by weight; and

a colloidal silica solution containing 15 - 30 part by weight of silica solid matter with respect to 100 part by  
10 weight of the sintered powder.

2. The coating composition according to claim 1, wherein the Fe-Si-based composite compound sintered powder has a surface oxide layer formed on a surface thereof and  
15 containing oxygen less than 2.0%.

3. The coating composition according to claim 1, further comprising at least one selected from the group consisting of fine SiO<sub>2</sub> powder, alumina powder and alumina  
20 sol by 0.2 - 3.5 part by weight with respect to 100 part by weight of the Fe-Si-based composite compound sintered powder.

4. The coating composition according to claim 1,  
25 wherein the Fe-Si-based composite compound sintered

powder substantially comprises  $\text{FeSi}_2$ ,  $\text{FeSi}$ ,  $\text{Fe}_5\text{Si}_3$ , or  $\text{Fe}_3\text{Si}$ , and comprises the sintered powder of  $\text{FeSi}_2 + \text{FeSi}$  in excess of 90 wt% with respect to the weight of the Fe-Si-based sintered powder.

5

5. A method for manufacturing a high silicon electrical steel sheet, comprising the steps of:

coating and drying the coating composition as recited in any of claims 1 to 4 on a surface of a steel sheet  
10 containing 2.0 - 3.3 wt% Si; and

diffusion annealing the dried steel sheet in a nitrogen gas atmosphere containing 20% or more hydrogen at a temperature range of 1000 - 1200 °C.

15 6. The method according to claim 5, wherein the drying step is performed at a temperature of 200 - 700 °C.

7. The method according to claim 5, wherein the diffusion annealing step is performed at a temperature of  
20 1050 - 1200 °C.

8. In a method for manufacturing a high silicon grain-oriented electrical steel sheet, comprising the steps of: reheating and hot-rolling a steel slab to produce a hot  
25 rolled steel sheet; annealing a hot rolled sheet and cold

rolling the steel sheet to adjust a thickness of the steel sheet; decarburization annealing the steel sheet; and secondary recrystallization annealing the steel sheet,

the improved method further comprising the step of:

5 pickling the surface of the grain-oriented electrical steel sheet where the secondary recrystallization is completed to remove a surface oxide layer;

coating and drying the coating composition as recited in any of claims 1 to 4 on the surface of the pickled  
10 electrical steel sheet; and

diffusion annealing the dried electrical steel sheet in a nitrogen gas atmosphere containing 20% or more hydrogen at a temperature range of 1000 - 1200 °C.

15 9. The method according to claim 8, wherein the steel sheet to be coated with the coating composition contains 2.9 - 3.3wt% Si with respect to the weight of the steel sheet.

20 10. The method according to claim 8, wherein the steel sheet coated with the coating composition is dried at a temperature of 200 - 700 °C.

11. The method according to claim 8, wherein the  
25 steel sheet coated with the coating is diffusion annealed

at a temperature of 1050 - 1200 °C.

12. The method according to claim 8, wherein the coating composition is coated on the surface of the steel sheet so as to satisfy the following formulas 1 and 2:

$Y - 5 \leq \text{coated amount} \leq Y + 5$  ----- formula 1, and

$Y(\text{g/m}^2) = 7650t(x1 - x2)/(A - 14.4)$  --- formula 2,

where 't' is a thickness of matrix material, A is a Si content (%) in the Fe-Si-based sintered powder, x1 is a target Si content (%) of matrix material, and x2 is an initial Si content of matrix material.

13. In a method for manufacturing a high silicon non-oriented electrical steel sheet, comprising the steps of: reheating and hot-rolling a steel slab to produce a hot-rolled steel sheet; annealing the hot-rolled steel sheet and cold rolling an annealed steel sheet to adjust a thickness of the steel sheet; recrystallization annealing the cold-rolled steel sheet,

the improved method further comprising the step of:

coating and drying the coating composition as recited in any of claims 1 to 4 on the surface of the cold rolled steel sheet; and

diffusion annealing the dried electrical steel sheet in a nitrogen gas atmosphere containing 20% or more

hydrogen at a temperature range of 1000 - 1200 °C.

14. The method according to claim 13, wherein the steel sheet to be coated with the coating composition  
5 contains 2.9 - 3.3 wt% Si.

15. The method according to claim 13, wherein the steel sheet coated with the coating composition is dried at a temperature of 200 - 700 °C.

10

16. The method according to claim 13, wherein the steel sheet coated with the coating composition is homogenized at a temperature of 1050 - 1200 °C.

17. The method according to claim 13, wherein prior to coating the coating composition, the cold rolled steel sheet is intermediate-annealed such that a total oxygen content in a surface oxide layer of the steel sheet is 210 - 420 ppm.

20

18. The method according to claim 17, wherein the cold rolled steel sheet is intermediate-annealed at a temperature range of 950 - 1100 °C.

25 19. The method according to claim 17, wherein the

cold rolled steel sheet is intermediate-annealed in a nitrogen atmosphere containing 50 % or more hydrogen and a moisture atmosphere with a dew point ( $P_{H_2O}/P_{H_2}$ ): 0.06 - 0.30.

5        20. The method according to claim 13, wherein the coating composition is coated on the surface of the steel sheet so as to satisfy the following formulas 1 and 2:

$Y - 5 \leq \text{coated amount} \leq Y + 5$  ----- formula 1, and

$Y(\text{g/m}^2) = 7650t(x1 - x2)/(A - 14.4)$  --- formula 2,

10        where 't' is a thickness of matrix material, A is a Si content (%) in the Fe-Si-based sintered powder, x1 is a target Si content (%) of matrix material, and x2 is an initial Si content of matrix material.
